Bioforsk
Organic
and Farm
Tingvoll

Anaerobic digestion may be a feasible way for organic farmers to:

- ❖ Produce sustainable bioenergy and fertilizers for crops.
- ❖ Recycle animal slurries and plant residues on the farm.

Effects of

Main questions and concerns

Biofo
Orgar
and F
Tingv

Do the residues from anaerobic digestion impact

- ❖ **the biodiversity of the soil fauna and the microorganisms – as well as their function?**
- ❖ **the physicochemical properties of the soil?**
- ❖ **the fertility of the soil?**

The main aim of the SoilEffects project is to establish a field experiment to compare long-term effects of anaerobically digested vs. non-digested manure (slurry) on crucial soil physical, chemical and biological characteristics.

Secondary aims are to:

- ❖ Establish a long-term field experiment within Tingvoll research farm and conduct the initial site characterization.
- ❖ Observe effects of the early transition period (3Y) on soil fauna (earthworms and other key-fauna organisms).
- ❖ Observe effects of the early transition period on soil physical, chemical and **microbiological conditions** (soil density; soil pH, nutrients, organic matter content and quality; **accumulated soil respiration, microbial community diversity**).
- ❖ Measure the effect of digested manure on the local Tingvoll earthworm population by in vitro pot experiments.
- ❖ Characterize the **activity of microorganisms** and important members of soil fauna (springtails).

The experimental plots were numbered 1-40 (3mx8m), and the five treatments were randomly assigned between the plots in each of four blocks.

	T	1 UH	2 DH	3 UL	4 DL	5 N	6 DH	7 UL	8 UH	9 DL	10 N	
	T	11 DL	12 N	13 DH	14 UH	15 UL	16 UL	17 N	18 UH	19 DL	20 DH	
		21 DL	22 UL	23 UH	24 DH	25 N	26 DL	27 UH	28 N	29 UL	30 DH	T
		31 DL	32 UH	33 N	34 UL	35 DH	36 DL	37 UH	38 UL	39 DH	40 N	T

Manure treatments:

- Control treatment with no manure = N
- Undigested slurry, low level = UL
- Undigested slurry, high level = UH
- Digested slurry, low level = DL
- Digested slurry, high level = DH

- Manure application per year
- Arable L/H: 85/170 kg N/ha
- Perennial L/H: 110/220 kg N/ha

Analyses and tests

Soil physical/chemical parameters

Plant nutrients

Crop yields

Weeds

Manures/digestate characteristics

Soil content of available organic carbon

Biological parameters

Earth worm species and abundance

Collembola species and abundance

Microbial community - diversity and size (PLFA)

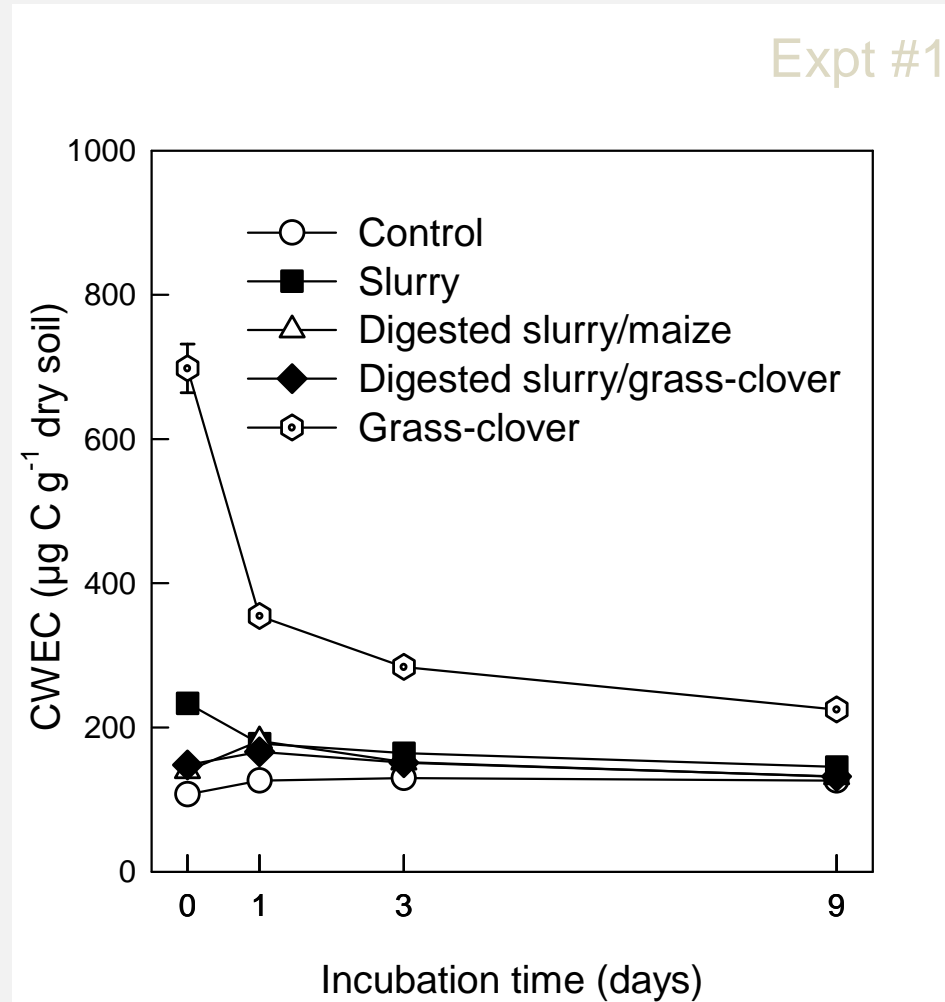

We measure soil available organic C – because it governs the response of the microbial community.

Available org. C = cold-water extractable C (CWEC)

Grass-clover contains most available org. carbon

Raw slurry contains slightly more org. carbon than digested materials

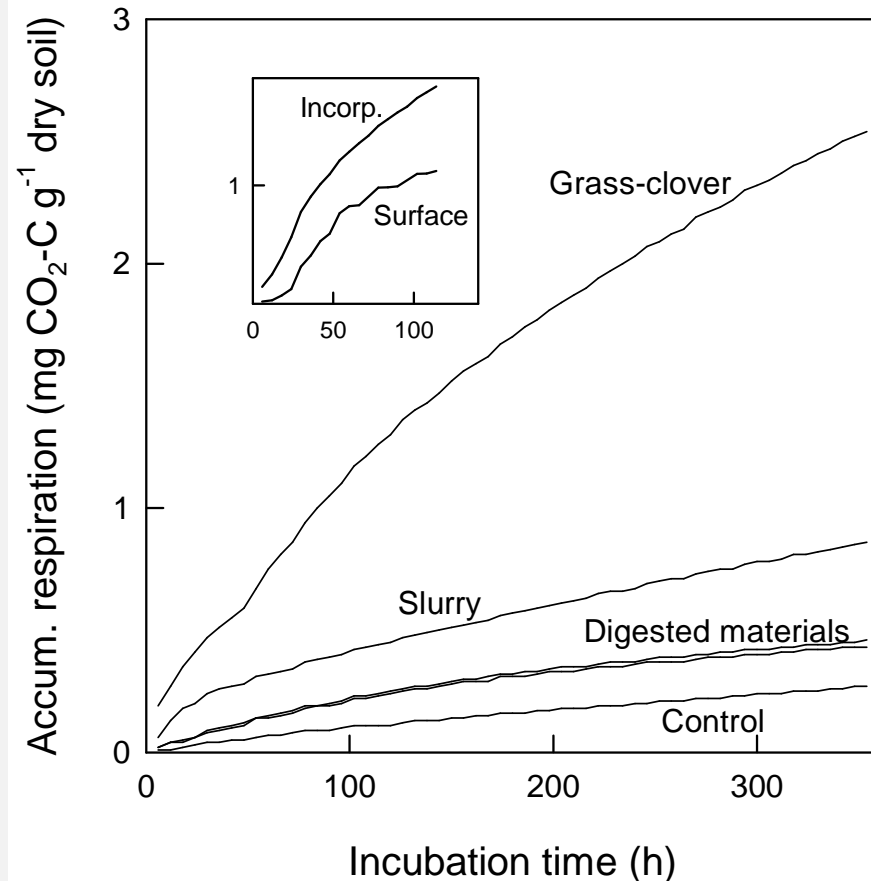

Carbon respired by microorganisms after addition of digested materials to soil (respirometer)

The materials containing most available org. C are turned over most quickly - and emit most CO₂

Expt #2

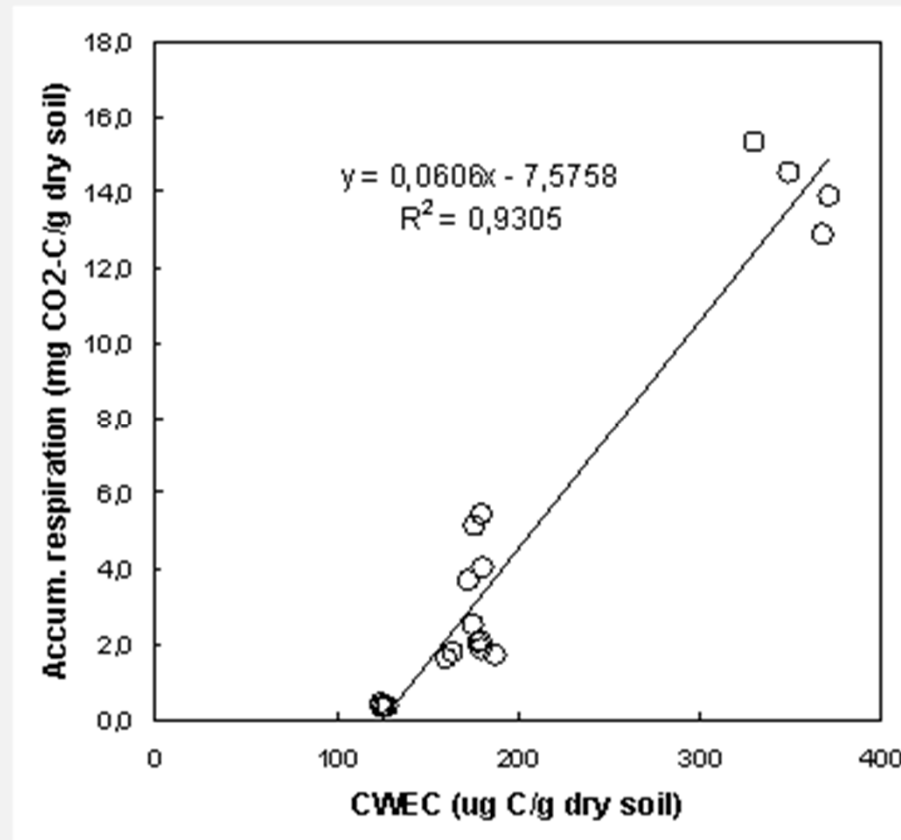

Tight relationship between the available carbon (CWEC) pool and the microbial respiration.

There is a close relationship between soil respiration and the CWEC applied with the residual materials.

So the content of this type of C in the slurries is important for the microbial community!

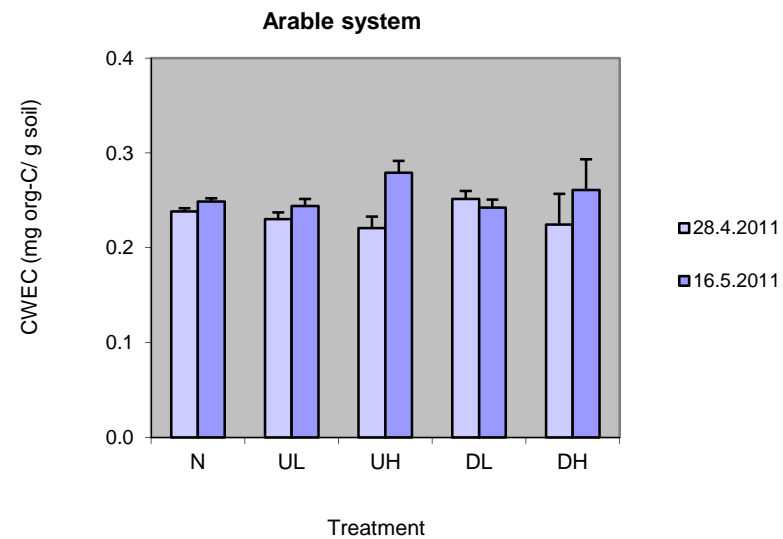

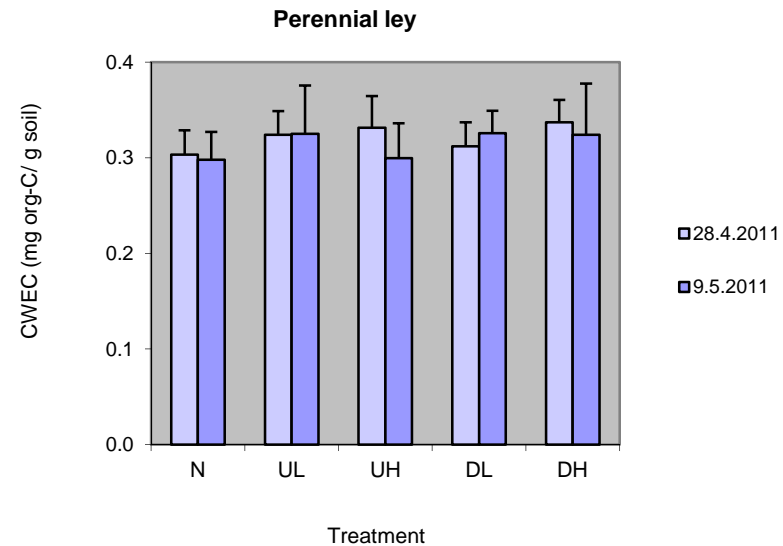

SoilEffects

Cold-water extractable organic C (CWEC) in spring 2011

The soil was sampled before fertilization and five days after fertilization

The CWEC was not much different among treatments but higher in perennial than in arable system

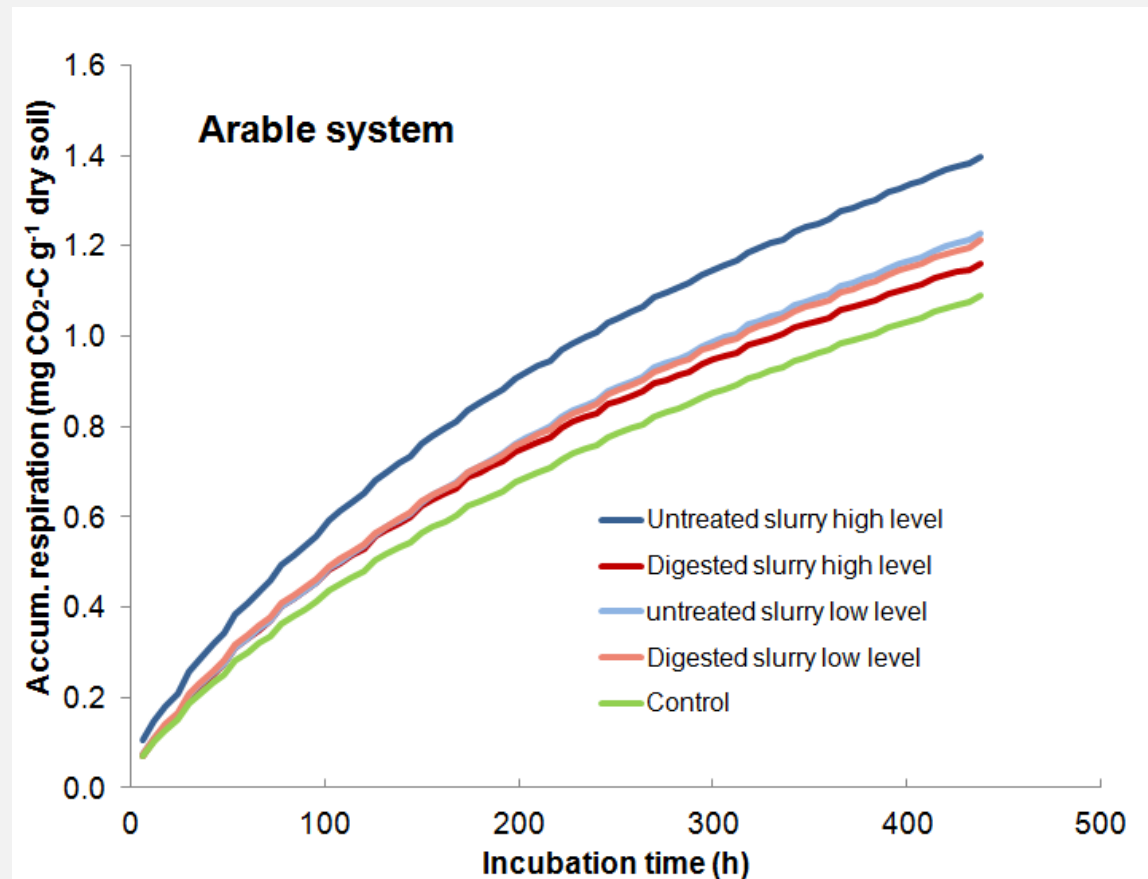

SoilEffects

Accumulated respiration from soil sampled in arable system in spring 2011

Untreated slurry at high level respire most – controls respire the least

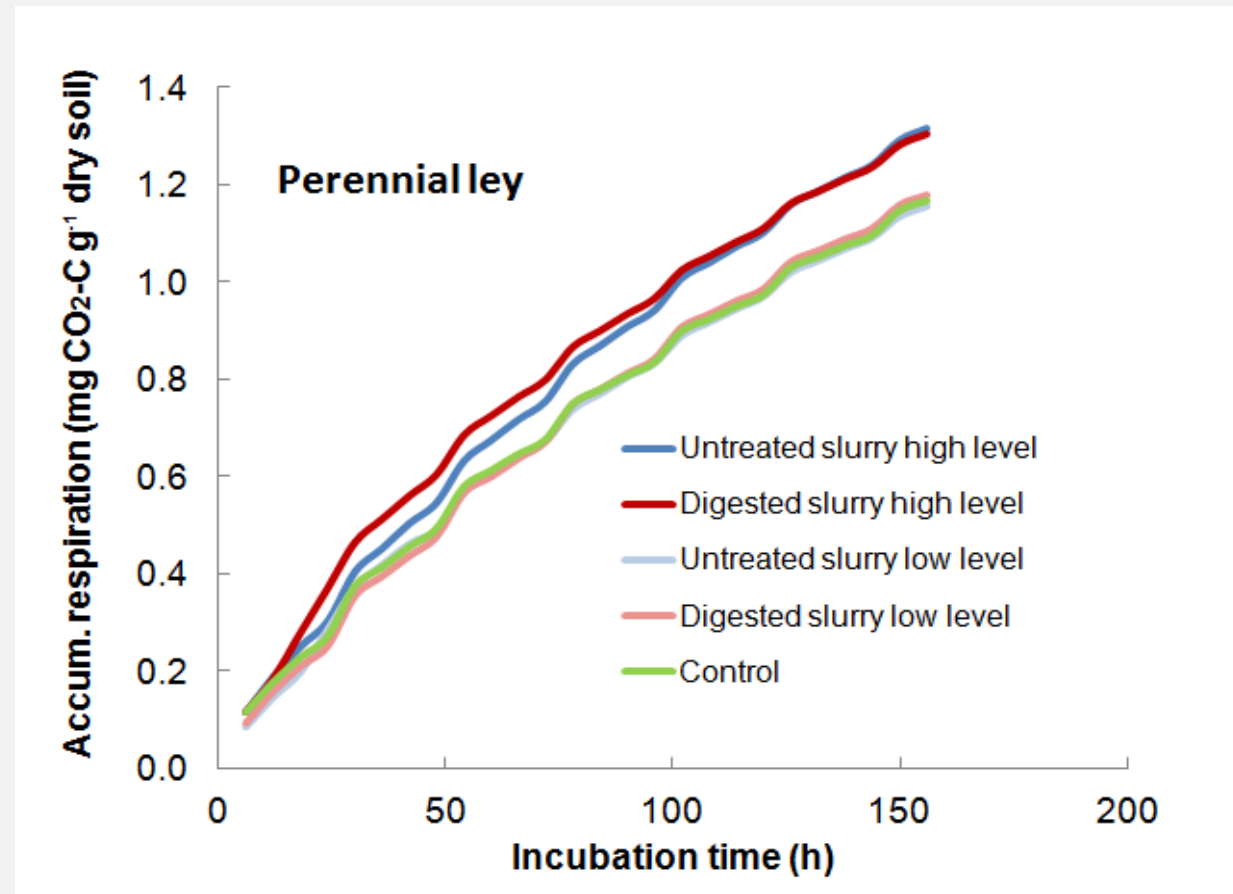

SoilEffects

Accumulated respiration from soil sampled in perennial system in spring 2011

Untreated/digested slurry at high level respire most

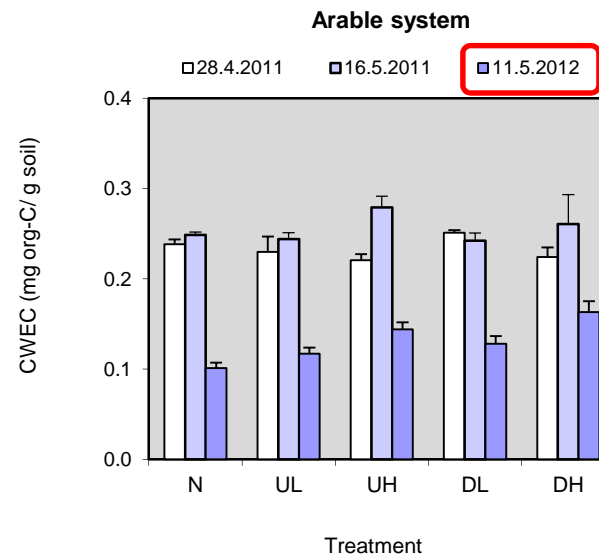

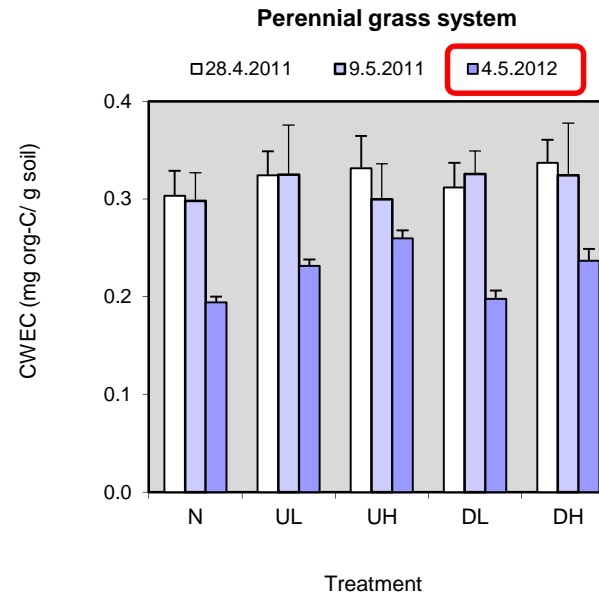

Soil Effects

CWEC somewhat lower in 2012 than in 2011, but follows the amount of manure applied

The difference between 2011 and 2012 maybe reflects differences in microbial biomass (can vary a lot between years) and with factors like crop type, precipitation, temperature etc.

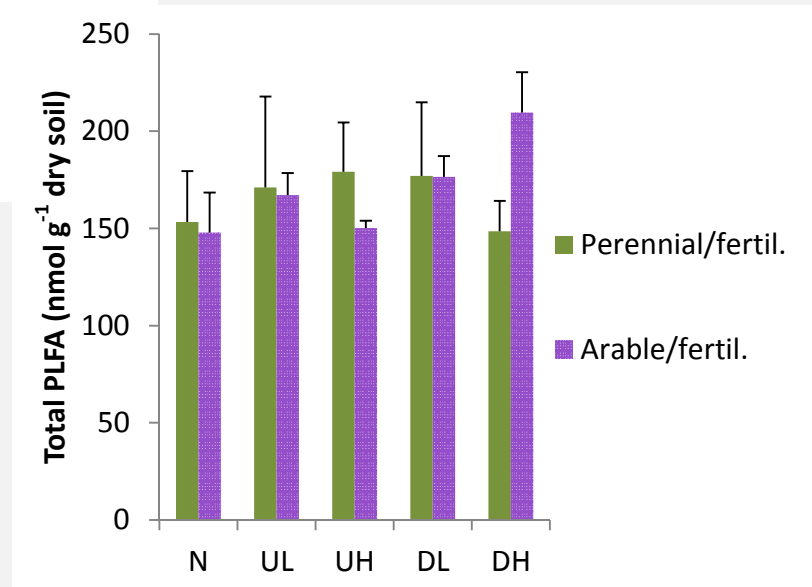

Soil microbial biomass as indicated by total PLFA (2011)

and - in 2013

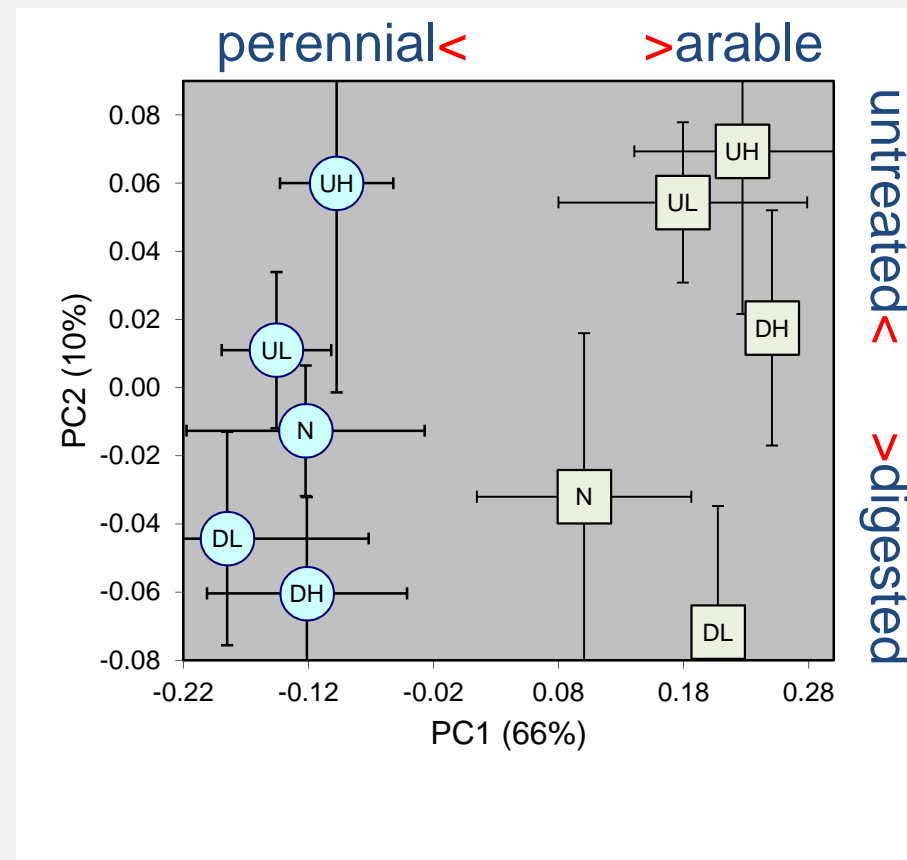

PLFA: phospholipid fatty acid analysis
 Indicates microbial biomass and
 community structure

Score plot from a principal component analysis of 26 PLFAs from soil sampled in the arable (squares) and perennial (circles) crop systems; five days after application of slurries in 2011.

The type of cropping system has more impact on the microbial community than the type and amount of material applied to the soil.

Conclusions

- ❖ The type of the cropping system seem to have more impact on the soil microbial community than the type of the applied manures.
- ❖ A substantial proportion of the organic C in the pristine slurry may be respired quickly after application – not contributing to the more resistant pool of organic C in the soil.
- ❖ The microbial community seems not impacted by the use of digested slurries compared to pristine slurry.
- ❖ A long-term experiments (20-30Y) is needed (and intended) to measure the effects of repeated application in many years – obviously.

How does all this fit into an “innovative strategy for sustainable plant nutrition”?

Anaerobic digestion may:

- ❖ Improve recycling of organic matter on farm.
- ❖ Improve possibility for utilizing organic matter from off-farm sources through anaerobic digestion to replenish most of the nutrients (N, P, K etc.).
- ❖ In this way may free some of the field areas otherwise used for nitrogen fixation so that they can be utilized for other purposes.

(SoilEffects was granted by the Research Council of Norway and the Agricultural Agreement Fund)
